DT Conference; Meeting Abstract

LA English

AB Most microfluidic devices are constructed by photo-lithog. methods using silicon or glass substrates, by rapid prototyping of poly(dimethylsiloxane) elastomers, or by conventional machining. We have developed an alternative method for producing microfluidic devices termed Surface Tension-Confined Microfluidics (STCM). STCM exploits wetting behavior and capillarity for guiding **liqs.** along 2-D patterned

surfaces sepd. by a thin spacer. With no sidewalls, fluid movement is confined to paths by surface tension. Very intricate flow patterns, dead-ended flow paths, bubble-free filling of large chambers, and **multilayer** configurations can be easily obtained with no necessity for air vents. Furthermore, the two-dimensional nature of such devices and the ability to use inexpensive polymeric substrates may permit economical **fabrication** compared with conventional microfluidic devices. Devices were typically **fabricated** using polypropylene plates. The pattern of **hydrophilic** flow paths was generated using "reactive ink" (RI) technol. In this case, the RI consisted of a sol-gel precursor, catalyst, and propanol as a solvent. A Hewlett-Packard plotter with a modified pen was used for patterning. Double-sided tape provided 90 .mu.m spacers between the two surfaces. A model for the balance of **hydrophilic** / **hydrophobic** forces assocd. with STCM has been derived. This model considers the tendency of a **liq.** (viz. Water) to wet **hydrophilic** paths vis-a-vis the energy penalty for creation of air-**liq.** interfaces perpendicular to the paths due to **hydrophobic** 'curbs'. Predictions of crit. width to height ratios agree reasonably well with exptl. data. Microfluidics applications envisaged for STCM include the prodn. of inexpensive disposable diagnostic devices. Along these lines, we have shown that complex media such as whole blood is readily "guided" on micropaths.

TI Neutron reflectivity at the solid/**liquid** interface: examples of applications in biophysics

DT Journal; General Review

LA English

AB A review with 54 refs. Over the last 20 yr, neutron reflection has emerged as a powerful technique for investigating inhomogeneities across an interface, inhomogeneities either in compn. or magnetization. By measuring the reflected over the incoming intensity of a well collimated beam striking at an interface, as a function of the incident angle and wavelength, the concn. profile giving rise to a reflectivity curve is calcd. The success of neutron reflection arises from the fact that, because of the short wavelengths available, it has a resoln. of a fraction of a nanometer, so that information is gained at the mol. level. Unlike x-rays it is not destructive and can be used at buried interfaces, which are not easily accessible to other techniques, such as **liq.**/**liq.** or solid/**liq.**, as well as at solid/air and **liq.**/air interfaces. It is particularly useful for soft matter studies since neutrons are strongly scattered by light atoms like H, C, O and N of which most org. and biol. **materials** are formed. Moreover, the nuclei of different isotopes of the same element scatter neutrons with different amplitude and sometimes, as in the case of protons and deuterons, with opposite phase. This allows the use of the method of contrast variation, described below, and different parts of the interface may be highlighted. For biophysics studies, a major advantage of reflectivity over other scattering techniques is that the required sample quantity is very small (<10<sup>-6</sup> g) and it is therefore suitable for work with expensive or rare macromols. While specular reflection (angle of incoming beam equal to angle of reflected beam) gives information in the direction perpendicular to the interface, the lateral structure of the interface may be probed by the nonspecular scattering measured at reflection angles different from the specular one. This technique is widely used with x-rays while there are far fewer data in the neutron case

due to the smaller intensity of neutron beams. An example relevant in biophysics where the neutron technique has been applied is the off-specular scattering from highly oriented multilamellar phospholipid membranes. Neutron reflection is now being used for studies of surface chem. (surfactants, polymers, lipids, proteins and mixts. adsorbed at liq./fluid and solid/fluid interfaces), surface magnetism (ultrathin Fe films, magnetic **multilayers**, superconductors) and solid films (Langmuir-Blodgett films, thin solid films, **multilayers**, polymer films). The no. of reflectometers in the neutron facilities all around the world is increasing although the use of the technique is not yet very common because the availability of beam time is restricted by cost. Since many biol. processes occur at interfaces, the possibility of using neutron reflection to study structural and kinetic aspects of model as well as real biol. systems is of considerable interest. However, the no. of such expts. so far performed is small. The reason for this is probably because it is well known that the most effective use of neutron reflection involves extensive deuterium substitution and this is not usually an available option in biol. systems. This problem may be partially solved by deuteriating other parts of the interface as described by Fragneto et al. In this paper we shall conc. on the use of specular neutron reflection at the solid/liq. interface, less studied than the solid/air or liq./air interfaces, although technol. more important. After a brief introduction to the theory and measurement of neutron reflectivity, solid/liq. interfaces both from **hydrophilic** and **hydrophobic** solids will be described. Three examples of applications in biophysics will be given: (1) The adsorption of two proteins, .beta.-casein and .beta.-lactoglobulin, on **hydrophobic** silicon; (2) The interaction of the peptide p-Antp43-58 with phospholipid bilayers deposited on silicon; (3) The fluid floating bilayer, a new model for biol. membranes.

AB A breathable diaper, feminine hygiene, or like disposable sanitary product construction having a cloth-like outer surface and including a plurality of **materials** from the skin-facing side outwardly, a topsheet, a core, an optional barrier, and a backsheet is disclosed. The topsheet is formed of **liq.-** and vapor-permeable **hydrophilic material**, and the core is formed of highly absorbent **material** disposed outwardly of the topsheet for absorbing **liq.** received through the topsheet. The core has an inner surface in **liq.** communication the said topsheet and an outer surface. The optional barrier is formed of a **multilayer** non-woven **material** which is **hydrophobic** and vapor-permeable for limiting the outward escape of **liq.** therethrough while enabling the outward escape of heat and water vapor therethrough. The barrier has a base disposed adjacent the core outer surface. The backsheet is formed of a **multilayer** non-woven **material** which is **hydrophobic** and vapor permeable for limiting the outward escape of **liq.** therethrough while enabling the outward escape of heat and water vapor therethrough. The backsheet is disposed at least partially as an outer surface of the diaper. At least one of the optional barrier **material** and the backsheet **material** has at least two meltblown layers. A prefabricated polypropylene non-woven substrate construction having meltblown (M) and spunbond (S) fibers in a configuration of S-M-S at a level of 7-4-7 g/m2 was used as a base substrate **material**. Various samples were created by applying a single meltblown layer to an SMS substrate to create a new barrier sheet. The spunbond layers of the substrate were made from Exxon 3445, and the meltblown layer of the substrate was made from Montell 3495G resin. The resultant SMSM **fabric** had a nice soft hand and with good phys. properties.

AB Polarized films are described which comprise asym. chromophores linked head-to-head by alternating two different kinds of bridging groups. One of the bridging groups contains one or more ionic groups, and the other bridging group contains one or more non-ionic, **hydrophilic** groups. The chromophores may be nonlinear optical chromophores. Langmuir-Blodgett (LB) film deposition methods are also described in which a layer of a nonaq. soln. of one polymer is spread on a subphase of an aq. soln. of the other in a Langmuir-Blodgett trough, a mol. bilayer of the two polymers is allowed to form by waiting 1-60 min, and the bilayer is then compressed while maintaining a gas-**liq.** surface pressure of 20-90% of the min. pressure required to collapse the bilayer; a multilayered film may then be formed by repeated dipping of a substrate. An electrooptical film which has never undergone elec.-field poling nor high temp. treatment may be produced. This eliminates the diln. effect of the long **hydrophobic** alkyl groups, and creates stronger ionic bonds between the polymer chains and reduces the time to make a film of a given thickness by at least half by virtue of depositing two polymer layers per stroke.

AB A **multilayer** device is comprised of .gtoreq.1 layer of **liq.**-absorbing polymeric **material** which increases in vol. on absorbing **liq.**, bound to .gtoreq.1 nonabsorbing or less absorbent layer so as to cause deformation of the device upon **liq.** absorption. If a bilayer laminate of sheets of absorbent and less absorbent **materials** is rolled into a tube, the tube will shrink or expand in diam. upon **liq.** absorption, depending on which layer is on the outside. The device may be used as a seal for tubular conduits, or in helical configuration in a self-expandable intraluminal vascular stent. Thus, a **hydrophobic** layer of biodegradable polydioxanone was superimposed on a **hydrophilic** composite layer of polydioxanone contg. 20% gelatin particles; the bilayer was bonded by heating. Strips of the bilayer 1.8 mm wide were wrapped on 3.0-4.0-mm diam. glass tubes, heated at 95.degree. for 15 min, and cooled to form stents. These stents, when placed in water, expanded from 4.0 to 5.6 mm outside diam.

AB A sheet pack which has a **multilayer moisture**-permeable support, including a **hydrophobic** layer and a **hydrophilic** layer impregnated with a cosmetic substance, is provided for **moisturizing** and cleansing the skin, absorbing sebum, and removing keratotic plugs. This pack does not have a sticky surface, completes the formation of a film in a relatively short period of time, is not easily torn during removal by peeling, and does not leave a film residue on the skin surface. The **hydrophobic** layer, which may be composed of synthetic fibers, is on the surface of the pack and is accordingly placed adjacent to the skin; the **hydrophilic** layer may consist of natural fibers, rayon, cellulose acetate, or surfactant-treated **hydrophobic** fibers. The cosmetic substance is a film-forming polymer which may include a humectant, a sebum-absorbing inorg. substance, a salt-forming polymer for keratotic plug removal, etc. Thus, a **hydrophobic** web of polypropylene fibers 0.18 mm thick was thermally bonded to a **hydrophilic** web 0.12 mm thick composed of 40 wt.% polypropylene fibers and 60 wt.% rayon fibers. The **hydrophilic** side of this bilayer was laminated to a polypropylene release sheet covered with a 300-.mu.m layer of a film-forming cosmetic soln. contg. poly[(methacryloyloxyethyl)trimethylammonium chloride] 25.0, glycerol 5.0, EtOH 10.0, polyoxyethylene-hardened castor oil 0.2, methylparaben 0.1, perfume, and water 54.7 wt.%, and the resulting sheet pack was dried at 80.degree..

AB	The films, useful for food packagings, photog. film linings, etc., comprise plastic films, successively laminated with (A) <b>hydrophilic</b> polymer layers with thickness (T) 1-10 .mu.m, (B) <b>hydrophobic</b> polymer layers with T 0.01-4 .mu.m, and (C) layers with T 0.1-10 .mu.m mainly composed of <b>hydrophobic</b> polymers (HBP) and <b>hydrophilic</b> polymers (HPP) at ratio HBP/HPP = 70/30-95/5, wherein particles of HBP with av. particle diam. (PD) 0.01-0.5 .mu.m are dispersed in the continuous layers of HPP and max. value of particle distance of HBP are .ltoreq.1/10 to PD. The layer-C may contains 5-25 parts (for HBP + HPP 100 parts) crosslinking agents selected from mucohalogenic acids, aldehydes, active vinyl compds. active halogen compds., aziridines, N-methylol compds., chromic acids, N-carbamoylpyridinium salts, and haloamidinium salts. Thus, (a) a mixt. of 50 g gelatin and 0.4 g 1,3-vinylsulfonyl-2-propanol, (b) a butadiene copolymer latex, and (c) a mixt. of 89:11 vinylidene chloride-Me methacrylate copolymer latex prepd. by sheed polymn. 85, gelatin 15, and				

an aziridine crosslinking agent 10 parts were applied to a PET substrate successively to give a product.

AB Disclosed is a **liq.**-suspension controlled-release enteric-coated pharmaceutical formulation for the administration of naproxen, comprising (a) microgranules of naproxen and an excipient; (b) four successive coats of polymeric **hydrophilic** and **hydrophobic materials**, at least the innermost of the coats imparting controlled-release properties to the naproxen according to a predetd. release profile, and at least the outermost of the coats imparting resistance to dissoln. in gastric fluids; and (c) a **liq.** administration vehicle. This compn. enables the oral administration of naproxen as a single daily dose and avoids detrimental effects of prolonged contact of naproxen with the gastric mucosa thus aiding oral intake and minimizing the drug's typical side effects. For example, microgranules were prepd. from a mixt. contg. naproxen, PVP, and lactose and coated with a 1st coating compn. contg. Et cellulose, di-Et phthalate, PEG, ethanol, and chloroform, followed by a 2nd **hydrophilic** coating compn. contg. Eudragit E, acetone, and iso-Pr alc., a 3rd lipophilic coating compn. contg. glyceryl monostearate, white beeswax, cetyl alc., stearyl alc., chloroform, and methanol, and a 4th enteric coating compn. contg. cellulose acetate phthalate, di-Et phthalate, acetone, and isopropanol.

AB A no. of triple chained ammonium amphiphiles have been synthesized with cyano- and nitrobiphenyl, and azobenzene mesogenic moieties at the termini of their **hydrophobic** chain. These compds. exhibit **liq** . cryst. behavior and form stable monolayers at the water-air interface. The monolayer give Z-type transfer onto **hydrophilic** quartz. However, the transferred **material** reorganizes and the morphol. of the film appears to depend on the thermotropic properties. For the cyanoazobenzene contg. Langmuir-Blodgett **multilayers**, mol. reorganization is obsd. upon irradiation with UV light or upon heating to give well ordered, centrosym., homeotropically aligned assemblies.

AB The title optical recording medium is composed of a support and a recording layer comprising a monolayer or **multilayers** of an org. compd. having intramol. **hydrophilic** and **hydrophobic** parts, in which the monolayer (or built-up layer) is prepd. by spreading a

soln. of the compd. on a host liq. deposited on the support surface while regulating the pH of the soln. The medium has high recording d. and good S/N ratio. The compd. (I) was mixed with arachidic acid and octadecane at equal molar ratio in CHCl<sub>3</sub> and the soln. was spread on an aq. surface of CaCl<sub>2</sub> 0.05M soln. A built-up monolayer was obtained by repetitively transferring under a surface pressure of 28 dyne/cm on a quartz glass substrate. The built-up layer was coated using vacuum-deposition with a 300-Å thick Al layer.

AB A multilayered test strip for the detn. of serum glucose by reflection spectrophotometry is described which consists of a transparent, **hydrophobic** support film (on the bottom); a reagent layer; a light-blocking layer; an adhesive layer; and a sample-spreading layer (on top) composed of a **fabric** treated to make it **hydrophilic**. In 1 example, the support film was a polyethylene terephthalate sheet.

The reagent layer contained glucose oxidase, peroxidase, 1,7-dihydroxynaphthalene, 4-aminoantipyrine, gelatin, and Nonion HS 210 (a polyoxyethylene alkyl Ph ether). The light-blocking layer was a soln. of gelatin and TiO<sub>2</sub> (1:8), and the adhesive layer contained gelatin and 0.2% Nonion HS 210. The sample-spreading layer was a piece of broadcloth which was treated with an aq. soln. of gelatin to make it **hydrophilic**. A 0.2% Nonion HS 210 soln. was applied to the test strip, and the layers were laminated together. A glucose-contg. soln. was applied to the strip, the strip was incubated at 37.degree. for 10 min, and the sample was analyzed by reflection spectrophotometry at 495 nm.

AB Microcapsules were prepd. by conventional techniques, i.e. by coacervation of a **hydrophilic** colloid, by phase sepn. of a high mol. wt. film former, by polymn. of a low mol. wt. polymer in the presence of a catalyst, or by the reaction of 2 different **materials** which reacted with one another on the interface of **hydrophobic** and **hydrophilic liqs.** in order to form, on the surface of minute drops, a high mol. wt. film at the interface between the **hydrophilic** and **hydrophobic liqs.** Defects in the capsule walls were filled in by forming a 2nd capsule layer through an interface reaction in which 2 different **materials** reacted with one another on the interface of **hydrophilic** and **hydrophobic liqs.** in order to form a high mol. wt. film

insol. in both **liqs.** Thus, a soln. of 1 g bisphenol A Na salt in 30 g H<sub>2</sub>O was dispersed and emulsified in a soln. of toluene 35, BuOAc 6, and poly(vinyl acetate) 3 g in order to form 10- $\mu$ . drops. The emulsified dispersion was heated to 40.degree. and a soln. of toluene 25, BuOAc 4, hexamethylene diisocyanate trimer 3, and tolylene diisocyanate-trimethylolpropane addn. compd. 1.0 g was added dropwise in 2 hr. The mixt. was stirred 4 hr at 40.degree. to form microcapsules contg. water in a polyurethane shell. After cooling the microcapsule dispersion to 30.degree., a soln. of 0.9 g terephthaloyl chloride in 15 g toluene was added dropwise in 1 hr. A polyester film. insol. in the solvents, formed on the microcapsules filling in and enclosing defects in the capsule walls. After sepn. from the solvents, the capsules could be stored 6 months at 40-60.degree. without any evapn. of water.

AB	<p>A <b>multilayer material</b> is used comprising a support such as a film together with Ag halide emulsion layers arranged in superimposition, the Ag halide emulsion layers being sepd. by intermediate layers inseparable therefrom and comprising a mixt. of a <b>hydrophilic</b> colloid such as gelatin and a <b>hydrophobic</b> colloid such as a condensation product of maleic acid anhydride with colophony with the <b>hydrophobic</b> colloid present in such an amt. as to make the layers impermeable to the aq. treating <b>liquids</b> used for obtaining the component picture in the Ag halide emulsion layer superimposed on the intermediate layer, the <b>hydrophobic</b> component being, however, capable of saponification, thus being rendered permeable for the aq. treating <b>liquids</b> employed for obtaining the component picture in the Ag halide emulsion layer arranged under the intermediate layer.</p>

AB The title films and **fabric** laminates having increased wet tensile strength, useful for surgical gowns, patient drapes, protective **garments**, etc., comprise a 1st **layer** of a **hydrophilic** polyether-polyamides block copolymer contg. 20-80% polyethylene glycol blocks and a 2nd **layer** of a **hydrophobic** polymer blend with specified properties, optionally laminated with a (non)**woven** or knitted **fabric**. A 0.0008-in extruded title film comprising 0.00064-in-thick 1st **layer** from a blend of a polyamide-polyether block copolymer stabilized by 500 ppm Irganox 1010 (Pebax MX-1657) 64.34, nylon 6 14.84, maleated polyethylene (Fusabond MB-110 D) 19.80, antioxidants 0.64, heat stabilizer 0.23, and UV stabilizer 0.15 parts, and a 0.00016-in-thick 2nd **layer** of a poly(tetramethylene glycol)-nylon 12 block copolymer (Pebax 4033) had moisture vapor transmission rate 2688 g/m<sup>2</sup>/day, tensile

strength (machine direction, 1st **layer** exposed to high-humidity source during testing) 7025 psi, and elongation at break 580%. The film passed a colored aq. Me2CHOH soln. strike-through test.
